CONVERGENT DISCRETIZATION OF HEAT AND WAVE MAP FLOWS TO SPHERES USING APPROXIMATE DISCRETE LAGRANGE MULTIPLIERS

SÖREN BARTELS*, CHRISTIAN LUBICH, AND ANDREAS PROHL

Abstract. We propose fully discrete schemes to approximate the harmonic map heat flow, and the wave map into spheres. The proposed finite-element based schemes preserve a unit length constraint at the nodes by means of approximate discrete Lagrange multipliers, satisfy a discrete energy law, and iterates are shown to converge to weak solutions of the continuous problem. Comparative computational studies are included to motivate finite-time blow-up behavior in both cases.

1. Introduction

Let \( \Omega \subset \mathbb{R}^d \) (for \( d \geq 1 \)) be a bounded domain, and \( S^{m-1} \subset \mathbb{R}^m \) (for \( m \geq 2 \)) the unit sphere. The energy of a map \( w : \Omega \rightarrow S^{m-1} \) is defined as

\[
E(w) = \frac{1}{2} \int_{\Omega} |\nabla w|^2 \, dx.
\]

Critical points are called weakly harmonic maps into the sphere [20], which are of interest in more extended models in micromagnetics [15], liquid crystal theory [1], color image denoising [22, 23, 25], or (in generalized form) in general relativity [18]. Related prototype nonstationary problems for solutions \( u : \Omega_T \rightarrow S^{m-1} \) are A) the \( L^2 \)-gradient flow for (1.1),

\[
\begin{align*}
\partial_t u - \Delta u &= |\nabla u|^2 u \quad &\text{in } \Omega_T := (0, T) \times \Omega, \\
\frac{\partial u}{\partial n} &= 0 \quad &\text{on } \partial \Omega_T := (0, T) \times \partial \Omega, \\
u(0, \cdot) &= u_0 \quad &\text{in } \Omega,
\end{align*}
\]

and B) the wave map flow into the sphere \( S^{m-1} \),

\[
\begin{align*}
\partial_{tt} u - \Delta u &= (|\nabla u|^2 - |u_t|^2) u \quad &\text{in } \Omega_T, \\
\frac{\partial u}{\partial n} &= 0 \quad &\text{on } \partial \Omega_T, \\
u(0, \cdot) &= u_0, \quad \partial_t u(0, \cdot) = v_0 \quad &\text{in } \Omega.
\end{align*}
\]

In both cases, static solutions are harmonic maps to the sphere; clearly, evolution is different in A) and B). For Problem A), existence of weak solutions can be found in [10]; the development of singularities in finite time, i.e., \( \limsup_{t \to T^-} \|u(t, \cdot)\|_{W^{1, \infty}} = \infty \), is shown in [11, 9] for equivariant initial data. As to Problem B), (stable self-similar) finite-time blow-up behavior of existing weak solutions (cf. [17, 7, 24]) is known in the (3+1)-dimensional case using equivariant initial data, and existence of \((k-)\)equivariant solutions (with ‘winding number’ \( k \geq 4 \)) in a \((2+1)\)-dimensional Minkowski space-time setting is known which show finite-time blow-up [16, 8].

Numerical analysis of Problems A) and B) is nontrivial for the following reasons:
1) In order to approximate (or construct in the limit) weak solutions in both cases A) and B) by using fully practical schemes based on finite elements, we cannot benefit from regularity properties of solutions in both cases, but need to verify crucial stability properties, like discrete sphere constraint and discrete energy identity.

2) Straightforward spatio-temporal discretizations, together with standard finite elements violate the sphere constraint, and lack a discrete energy law; see e.g. [3, 13].

3) Convergent penalization strategies of Problems A) and B) which use a Ginzburg-Landau penalty (with parameter $\varepsilon > 0$) to approximate the sphere constraint allow for convergent discretizations for every $\varepsilon > 0$; however, to specify this parameter in terms of discretization parameters is a nontrivial task, in particular in the context of blow-up behavior of weak solutions to these problems; cf. [6] for computational evidence for Problem B).

In [3, 4], a fully practical implicit scheme is given to solve Problem A), which is based on a reformulation of (1.2) using cross products ($m = 3$),

$$
\mathbf{u}_t + \mathbf{u} \times (\mathbf{u} \times \Delta \mathbf{u}) = 0 \quad \text{in } \Omega_T.
$$

Together with reduced spatial integration, midpoint formula, as well as projected discrete Laplacian, a lowest order conforming finite element discretization enjoys a discrete sphere constraint and discrete energy identity.

Unfortunately, this strategy is not successful for Problem B); instead, an explicit time-splitting energy law, and solutions unconditionally (sub-)converge to weak solutions; moreover, a simple scheme was proposed for Problem B) in [6], and conditional convergence towards weak solutions is verified; here the idea, which originally was given in [2] in a different context, is to discretize the following reformulation of (1.5), which uses special test-functions $\mathbf{w} \in C([0, T] \times \Omega, \mathbb{R}^m)$ which satisfy $\langle \mathbf{u}, \mathbf{w} \rangle = 0$ a.e. in $\Omega_T$, such that

$$
\int_0^T (\partial_t^2 \mathbf{u}, \mathbf{w}) \, dt + \int_0^T (\nabla \mathbf{u}, \nabla \mathbf{w}) \, dt = 0.
$$

In this work, we construct different convergent discretizations for both problems A) and B), which use approximate discrete Lagrange multipliers: To motivate the approach, recall that to describe the gradient flow for (1.1) requires mappings $\mathbf{u} : \Omega_T \to \mathbb{R}^m$, and a Lagrange multiplier $\lambda : \Omega_T \to \mathbb{R}^+$, such that

$$
\mathbf{u}_t - \Delta \mathbf{u} = \lambda \mathbf{u} \quad \text{and} \quad |\mathbf{u}| = 1 \quad \text{in } \Omega_T.
$$

In fact, $\lambda = |\nabla \mathbf{u}|^2$ is easy to verify in the present case, where the target manifold is the sphere. The following scheme uses an approximate discrete Lagrange multiplier to enforce both the discrete sphere constraint, i.e., unit length of (iterates of) finite element functions at nodes of a triangulation $T_h$, and a discrete energy law.

We employ some notation which is further detailed in Section 2. Let $V_h \subset W^{1,2}(\Omega)$ be the lowest order conforming finite element space subordinate to a triangulation $T_h$ of $\Omega$, and $V_h = [V_h]^m$. By $N_h$, we denote the set of all nodes associated with $T_h$. Below, $(\cdot, \cdot)_h$ denotes the discrete version (reduced integration) of the inner product in $L^2(\Omega, \mathbb{R}^m)$, and we use $d_k \varphi^n := k^{-1}(\varphi^n - \varphi^{n-1})$, and $\varphi^{n+1/2} := \frac{1}{2}(\varphi^{n+1} + \varphi^n)$ with $n \geq 1$, for a sequence $\{\varphi^n\}_{n \geq 0}$, and for an equidistant time-step size $k > 0$. Then, the approximation scheme for Problem A) reads as follows.

**Algorithm A.** For $n \geq 0$, let $U^n \in V_h$ be given, and find $(U^{n+1}, \lambda^{n+1}) \in V_h \times V_h$, such that

\begin{align}
(1.8) & \quad (d_t U^{n+1}, \Phi)_h + (\nabla U^{n+1/2}, \nabla \Phi) = (\lambda^{n+1} U^{n+1/2}, \Phi)_h \quad \forall \Phi \in V_h, \\
(1.9) & \quad |U^{n+1}(z)| = 1 \quad \forall z \in N_h.
\end{align}
As will be shown in Section 3, an explicit formula to compute $\lambda^{n+1} = \lambda^{n+1}(U^{n+1/2})$ is available; however, in contrast to the continuous Lagrange parameter above, its computation at a single node $z \in \mathcal{N}_h$ requires to consider values of $U^{n+1/2}$ at neighboring nodes — which accounts for finite sizes $k, h > 0$ in the discretization scheme. Conditional solvability of Algorithm A holds by Lemma 3.1. The method is devised such that a discrete energy identity holds: choose $\Phi = d_t U^{n+1}$ in (1.8), and use reduced integration for the first and last term, together with $|U^{n+1}(z)|^2 - |U^n(z)|^2 = 0$, for all $z \in \mathcal{N}_h$, to obtain

$$
\|d_t U^{n+1}\|_h^2 + (\nabla U^{n+1/2}, \nabla d_t U^{n+1}) = 0,
$$

and after summation over all iteration steps $0 \leq n \leq N$,

$$
E(U^{N+1}) + k \sum_{n=0}^N \|d_t U^{n+1}\|_h^2 = E(U^0).
$$

As is worked out in Section 3, this discrete energy law is then crucial to verify (subsequence) convergence of iterates from Algorithm A to weak solutions of (1.2)–(1.4); see Theorem 3.1.

**Remark 1.1.** Note that $\lambda^{n+1} \in V_h$ (for $n \geq 0$) is not the Lagrange multiplier associated to the discrete sphere constraint $|U^{n+1}(z)|^2 = 1$ for all $z \in \mathcal{N}_h$, since the right-hand side of (1.8) is modified from $(\lambda^{n+1} U^{n+1}, \Phi)_h$ to $(\lambda^{n+1} U^{n+1/2}, \Phi)_h$ to obtain the discrete energy law (1.10).

A similar program is now evident for the wave map problem (1.5)–(1.7), where (1.5) is of the form

$$
\partial_t u - \Delta u = \lambda u \quad \text{and} \quad |u| = 1 \quad \text{in} \quad \Omega_T,
$$

with $\lambda = (|\nabla u|^2 - |u|^2)$ in the present form. In Section 4, we show conditional convergence of the following implicit discretization, which again uses approximate discrete Lagrange multipliers.

**Algorithm B.** For $n \geq 1$, let $U^n, U^{n-1} \in V_h$ be given, and find $(U^{n+1}, \lambda^{n+1}) \in V_h \times V_h$, such that

$$
d_t^2 U^{n+1}(\Phi)_h + (\nabla U^{n+1/2}, \nabla \Phi) = (\lambda^{n+1} U^{n+1/2}, \Phi)_h \quad \forall \Phi \in V_h,
$$

$$
|U^{n+1}(z)| = 1 \quad \forall z \in \mathcal{N}_h.
$$

The second starting value is chosen as $U^1 = U^0 + k V^0 - \mu U^0$, where $V^0$ is the initial velocity and $\mu$ is chosen such that $|U^{n+1}(z)| = 1$ for all $z \in \mathcal{N}_h$. As for Problem A), a discrete energy law can be shown, using $E_h(V^n, W^n) = \frac{1}{2} \left[ \|V^n\|_h^2 + \|\nabla W^n\|^2 \right]$,

$$
E_h(d_t U^{N+1}, U^{N+1}) + \frac{k^2}{2} \sum_{n=1}^N \|d_t^2 U^{n+1}\|_h^2 = E_h(V^0, U^0) \quad (N \geq 1)
$$

and conditional solvability; cf. Lemma 4.1. As is evident from the second term in (1.13), Algorithm B uses numerical dissipation, while a symmetric and conservative discretization of (1.5)–(1.7), which replaces (1.11) by

$$
d_t^2 U^{n+1}(\Phi)_h + \left( \frac{1}{2} \nabla [U^{n+1} + U^{n-1}], \nabla \Phi \right) = \left( \frac{\lambda^n}{2} [U^{n+1} + U^{n-1}], \Phi \right)_h
$$

is discussed in Remark 4.1. However, in the analysis for Algorithm B in Section 4, its dissipative character is needed to conclude convergence of iterates towards weak solutions of (1.5)–(1.7); see Theorem 4.1.

The main result for the heat flow of harmonic maps is Theorem 3.1, which verifies subsequence convergence of iterates from the implicit Algorithm A towards weak solutions of Problem A), provided that $k \leq C h^2$; this (unexpected) mesh constraint is sufficient for solvability for finite $(k, h) > 0$, whereas both, the discrete energy law and the sphere constraint do not require mesh
constraints. We remark that no constraint is required in [3] for the special case where the target is the two-dimensional sphere. — For the wave-map equation, conditional convergence towards weak solutions of Problem B) is verified in Theorem 4.1; again, only Brouwer’s fixed-point argument to verify existence of iterates requires a mesh-constraint \( k \leq h^{\min(d/2,2)} \), while discrete energy law and sphere constraint hold unconditionally. For comparison, to validate a (slightly perturbed) discrete energy law and eventually conclude convergence for the splitting-based algorithm in [6] requires the more restrictive mesh-constraint \( k \leq o(h^{d/4}) \) to hold. Interestingly, the fixed point iterations employed to solve the nonlinear systems of equations in the numerical experiments reported in Section 5 seem to converge exactly under these constraints, which indicates that our results may be sharp.

The remainder is organized as follows: Section 2 collects some notations which are used throughout the paper. Section 3 verifies convergence of Algorithm A to obtain weak solutions of Problem A) in the limit \((k,h) \to 0\). Section 4 correspondingly shows convergence of Algorithm B towards Problem B). Computational experiments to motivate possible blow-up for both Problems are reported in Section 5, and are compared with corresponding studies in [3] (harmonic map heat flow), and [6] (wave map equation).

2. Preliminaries

Standard notation is adopted throughout this paper. \( \langle \cdot, \cdot \rangle \) denotes the standard inner product of the Euclidean space \( \mathbb{R}^d \), \( \langle \cdot, \cdot \rangle_{\Omega} \) is the standard \( L^2 \)-inner product over the domain \( \Omega \subset \mathbb{R}^d \). \( W^{\ell,p}(\Omega, \mathbb{R}^m) \) denotes the \((\ell, p)\)-Sobolev space of vector-valued functions, and \( \| \cdot \|_{W^{\ell,p}} \) its norm. Throughout this paper, \( C > 0 \) is used as a generic positive \((k, h)\)-independent constant which may take different values at different locations. We also introduce \( u_t := \partial_t u, \nabla u := (\partial_{x_1} u, \ldots, \partial_{x_d} u) \), \( D := (\partial_t, \nabla) \), and define the nonlinear Sobolev space

\[
W^{1,2}(\Omega, S^{m-1}) = \{ u \in W^{1,2}(\Omega, \mathbb{R}^m); u \in S^{m-1}\text{ a.e. in } \Omega \}.
\]

where boldface letters are used for vector-valued quantities.

For simplicity, let \( \Omega \) be a bounded polygonal (when \( d = 2 \)) or polyhedral (when \( d = 3 \)) domain. Let \( T_h \) denote a quasiuniform triangulation of \( \Omega \) into triangles or tetrahedra with mesh size \( h > 0 \) for \( n = 2 \) or \( n = 3 \), respectively. For a domain \( K \subset \mathbb{R}^d \), let \( P_1(K) \) stand for the set of all affine functions on \( K \). We define the Lagrange finite element spaces

\[
V_h := \{ w \in C(\overline{\Omega}); w|_K \in P_1(K) \text{ } \forall K \in T_h \}, \quad V_h := [V_h]^m.
\]

Let \( N_h \) denote the set of all nodes associated with the finite element space \( V_h \), and \( \{ \varphi_z; z \in N_h \} \) the nodal basis for \( V_h \); we define the following nodal interpolation operator \( I_h : C(\overline{\Omega}) \to V_h \) by

\[
I_h w := \sum_{z \in N_h} w(z) \varphi_z \quad \forall w \in C(\overline{\Omega}).
\]

For any two functions \( \mathbf{v}, \mathbf{w} \in C(\overline{\Omega}, \mathbb{R}^m) \), we define a discrete \( L^2 \)-inner product by

\[
(\mathbf{v}, \mathbf{w})_h := \int_{\Omega} I_h(\langle \mathbf{v}, \mathbf{w} \rangle) \, dx = \sum_{z \in N_h} \beta_z \langle \mathbf{v}(z), \mathbf{w}(z) \rangle,
\]

where \( \beta_z = \int_{\Omega} \varphi_z \, dx \), for all \( z \in N_h \). We also define \( \| \mathbf{w} \|_h := (\mathbf{w}, \mathbf{w})_{L^2}^{1/2} \). It is easy to check that there holds for all \( \mathbf{v}, \mathbf{w} \in V_h \),

\[
\| \mathbf{w} \|_{L^2} \leq \| \mathbf{w} \|_h \leq (d + 2)^{1/2} \| \mathbf{w} \|_{L^2},
\]

\[
(\mathbf{v}, \mathbf{w})_h - (\mathbf{v}, \mathbf{w}) \leq C h \| \mathbf{v} \|_{L^2} \| \nabla \mathbf{w} \|_{L^2}.
\]
3. Harmonic map heat flow to the sphere

We numerically approximate weak solutions of (1.2)–(1.4) in the sense of [20].

Definition 3.1. Given \( u_0 \in W^{1,2}(\Omega, S^{m-1}) \), a function \( u \in W^{1,2}(\Omega_T, \mathbb{R}^m) \) is called a weak solution of (1.2)–(1.4) if for all \( T > 0 \) there hold (i) \( u(0, \cdot) = u_0 \in W^{1,2}(\Omega, S^{m-1}) \) in the sense of traces, (ii) \( |u| = 1 \) almost everywhere in \( \Omega_T \), (iii) for almost all \( T' \in (0, T) \) there holds

\[
\frac{1}{2} \int_{\Omega} |\nabla u(T', x)|^2 \, dx + \int_{0}^{T'} \|\partial_t u(t, \cdot)\|^2 \, dt \leq \frac{1}{2} \int_{\Omega} |\nabla u_0(x)|^2 \, dx ,
\]

and (iv) for all \( \phi \in C^\infty(\overline{\Omega_T}, \mathbb{R}^m) \) there holds

\[
\int_{\Omega_T} \langle \partial_t u, u \wedge \phi \rangle \, dxdt + \int_{\Omega_T} \langle \nabla u, \nabla (u \wedge \phi) \rangle \, dxdt = 0 .
\]

Next, we verify solvability for Algorithm A for restricted choices \( k = \mathcal{O}(h^2) \), and quasiuniform meshes \( T_h \). The proof uses a regularization in a first step to apply Brouwer’s fixed-point theorem; then, solutions are shown to satisfy (3.3)–(3.4), and discrete versions of the sphere constraint and the energy law. In the following, we use the notation for the energy given in (1.1).

Lemma 3.1. Let \( T_h \) be a quasiuniform triangulation of \( \Omega \subset \mathbb{R}^d \), and \( U^0 \in V_h \) such that \( |U^0(z)| = 1 \) for all \( z \in N_h \). For sufficiently small \( \hat{C} = \hat{C}(\Omega, T_h) > 0 \) independent of \( k, h > 0 \) such that \( k \leq \hat{C}h^2 \), there exists \( U^{n+1} \in V_h \) which satisfies (3.3)–(3.4), enjoys \( |U^{n+1}(z)| = 1 \) for all \( z \in N_h \), and

\[
E(U^{N+1}) + k \sum_{n=0}^{N} \|d_t U^{n+1}\|_h^2 = E(U^0) \quad (N \geq 0) .
\]

Proof. Step 1. Fix \( n \geq 0 \). For every \( \varepsilon > 0 \), and all \( \Phi \in V_h \), define the continuous mapping \( F_\varepsilon : V_h \to V_h \), where

\[
(F_\varepsilon(W), \Phi) := \left( \frac{2}{k} (W - U^n), \Phi \right)_h + \langle \nabla W, \nabla \Phi \rangle - \sum_{z \in N_h} \left( \frac{\nabla W, \nabla z}{\beta_z \max\{|W(z)|^2, \varepsilon\}} \varphi_z W, \Phi \right)_h .
\]
We compute
\[
\left( \beta^{-1}_x (\nabla W, W(z) \otimes \nabla \varphi_z), |W|^2 \right)_h = \frac{|W(z)|^2}{\max\{|W(z)|^2, \varepsilon\}} (\nabla W, W(z) \otimes \nabla \varphi_z)
\]
(3.7)
\[
\leq \left( |\nabla W|, |\nabla W(z) \varphi_z| \right)_{\text{supp}(\nabla \varphi_z)}
\]
\[
\leq Ch^{-1} (|\nabla W|, |W(z)|)_{\text{supp}(\nabla \varphi_z)}
\]

For all $W = \Phi$ such that $\|W\|_h \geq \|U^n\|_h$, and values $k \leq \tilde{C} h^2$ for some existing $0 < \tilde{C} \equiv \tilde{C}(\Omega)$, on using Young’s inequality, and the fact that the number of nodes $y \in \mathcal{N}_h$ such that $(\nabla \varphi_y, \nabla \varphi_z) \neq 0$ is bounded independently of $h > 0$, we have
\[
(F_{\varepsilon}(W), W) \geq \frac{2}{k} (\|W\|^2_h - \langle U^n, W \rangle_h) + \|\nabla W\|^2 - Ch^{-1} \|\nabla W\| \|W\|_h
\]
\[
\geq \frac{2}{k} \|W\|^2_h \left( 1 - \frac{Ck}{h^2} \right) \|W\|_h - \|U^n\|_h + \frac{1}{2} \|\nabla W\|^2 \geq 0,
\]
and a corollary to Brouwer’s fixed-point theorem [19, p. 37] then implies existence of $U^{n+1/2} \in V_h$, such that $F_{\varepsilon}(U^{n+1/2}) = 0$.

**Step 2.** We show that $U^{n+1/2} \in V_h$ solves $F_0(U^{n+1/2}) = 0$. For this purpose, it suffices to show for all $z \in N_h$ (parallelogram identity)
\[
2|U^{n+1/2}(z)|^2 = 1 + |U^{n+1}(z)|^2 - \frac{k^2}{2} |d_t U^{n+1}(z)|^2 = 2 - \frac{k^2}{2} |d_t U^{n+1}(z)|^2 > 0.
\]

Thanks to (3.6), the iterate $U^{n+1} := 2U^{n+1/2} - U^n$ satisfies for all $\Phi \in V_h$,
\[
(d_t U^{n+1}, \Phi)_h + (\nabla U^{n+1/2}, \nabla \Phi) = \sum_{z \in \mathcal{N}_h} \left( \frac{(\nabla U^{n+1/2}, U^{n+1/2}(z) \otimes \nabla \varphi_z)}{\beta_x \max\{|U^{n+1/2}(z)|^2, \varepsilon\}} \varphi_z U^{n+1/2}, \Phi \right)_h.
\]

On putting $\Phi = d_t U^{n+1}(z) \varphi_z$ for $z \in \mathcal{N}_h$, and using properties of reduced integration with $|U^{n+1}(z)|^2 - |U^n(z)|^2 = 0$, and inverse estimates, we have
\[
\beta_x |d_t U^{n+1}(z)|^2 \leq \left| (\nabla U^{n+1/2}, d_t U^{n+1}(z) \nabla \varphi_z) \right|
\]
\[
\leq |d_t U^{n+1}(z)||\nabla U^{n+1/2}|_{L^\infty} \|
abla \varphi_z \|_{L^1}
\]
\[
\leq |d_t U^{n+1}(z)| Ch^{-2} \|U^{n+1/2}\|_{L^\infty} \|
abla \varphi_z \|_{L^1}.
\]

We may then conclude that $|d_t U^{n+1}(z)| \leq Ch^{-2}$. Hence, assertion (3.8) is valid for values $k \leq \tilde{C} h^2$, for some $\tilde{C} \equiv \tilde{C}(\Omega) > 0$.

Convergence behavior of iterates $\{U^n\}$ of Algorithm A towards weak solutions of (1.2)–(1.4) for $(k, h) \to 0$ is verified below. In the sequel, we define $U_{k, h} : \Omega_T \to S^{m-1}$, where for all $(t, x) \in [t_n, t_{n+1}] \times \Omega$,
\[
U_{k, h}(t, x) := \frac{t - t_n}{k} U^{n+1}(x) + \frac{t_{n+1} - t}{k} U^n(x),
\]
and $U_{k, h}^+(t, x) := \mathbf{U}^{n+1}(x)$ resp. $\mathbf{U}_{k, h}^+(t, x) := U^{n+1/2}(x)$ for all $(t, x) \in [t_n, t_{n+1}) \times \Omega$.

**Theorem 3.1.** Let the assumptions of Lemma 3.1 be valid, $E(u_0) < \infty$, and $U^0 \to u_0 \in W^{1,2}(\Omega, S^{m-1})$ for $h \to 0$. There exists a subsequence of $\{U_{k, h}\}$ which for $(k, h) \to 0$ converges weakly in $W^{1,2}(\Omega_T, \mathbb{R}^m)$ to a weak solution of (1.2)–(1.4).
\textbf{Proof.} Step 1. The bounds of Lemma 3.1 yield the existence of convergent subsequences \(\{U_{k,h}\}\), and \(u \in W^{1,2}(\Omega_T, \mathbb{R}^m)\) such that for \(k \leq \tilde{C}h^d\), and \(h \to 0\),

\[
U_{k,h}, U_{k,h}^+, \overline{U}_{k,h} \rightharpoonup u \quad \text{in} \quad L^\infty(0, T; W^{1,2}(\Omega, \mathbb{R}^m)),
\]

\[
U_{k,h}, U_{k,h}^+, \overline{U}_{k,h} \to u \quad \text{in} \quad L^2(\Omega_T, \mathbb{R}^m),
\]

\[
\partial_t U_{k,h} \to u_t \quad \text{in} \quad L^2(\Omega_T, \mathbb{R}^m).
\]

Since \(|U_{k,h}^+| = 1\) for all \(z \in \mathcal{N}_h\) and all \(t \in [0, T]\), there holds \(I_h[|U_{k,h}^+|^2] = 1\) for all \((t, x) \in [0, T] \times \overline{\Omega}\), and for all \(k \in T_h\)

\[
\|U_{k,h}^+|^2 - 1\|_{L^2(K)} \leq Ch\|\nabla [U_{k,h}^+|^2 - 1]\|_{L^2(K)} \leq Ch\|\nabla U_{k,h}^+\|_{L^2(K)}.
\]

As a consequence, \(|U_{k,h}^+| \to 1\) almost everywhere in \(\Omega_T\), and hence \(|u| = 1\) almost everywhere.

We use weak lower semicontinuity of norms and \(\overline{U}^0 \to u_0\) in \(W^{1,2}(\Omega, \mathbb{R}^m)\) to conclude from (3.5) that \(u \in W^{1,2}(\Omega_T, \mathbb{R}^m)\) satisfies (3.1). Since the trace operator is bounded and linear, it is weakly continuous as an operator from \(W^{1,2}(\Omega_T)\) into \(L^2(\Omega)\), and we deduce \(u(0, \cdot) = u_0\) in the sense of traces.

Step 2. It remains to verify property (3.2) for \(u\). For this purpose, we rewrite (3.3) as

(3.10)

\[
(\partial_t U_{k,h}(t, \cdot), \Phi)_h + (\nabla U_{k,h}(t, \cdot), \nabla \Phi) = \sum_{z \in \mathcal{N}_h} \left( \frac{(\nabla U_{k,h}(t, \cdot), U_{k,h}(t, z) \otimes \nabla \varphi_z)}{\beta_z(|U_{k,h}(z)|^2)} \varphi_z U_{k,h}(t, \cdot), \Phi \right)_h
\]

for \(\Phi \in \mathbf{V}_h\), and all \(t \in (0, T)\). — Let \(\Psi \in C^\infty(\overline{\Omega_T}, \mathbb{R}^m)\); thanks to \(\langle a \wedge b, a \rangle = 0\), the choice \(\Phi = I_h[\overline{U}_{k,h}(t, \cdot) \wedge \Psi(t, \cdot)]\) then leads to

(3.11)

\[
(\partial_t U_{k,h}(t, \cdot), \overline{U}_{k,h}(t, \cdot) \wedge \Psi(t, \cdot))_h + (\nabla U_{k,h}(t, \cdot), \nabla I_h[\overline{U}_{k,h}(t, \cdot) \wedge \Psi(t, \cdot)]) = 0.
\]

We compute

(3.12)

\[
(\partial_t U_{k,h}, \overline{U}_{k,h} \wedge \Psi)_h - (\partial_t u, u \wedge \Psi)
\]

\[
= (\partial_t U_{k,h}, I_h[\overline{U}_{k,h} \wedge \Psi])_h - (\partial_t U_{k,h}, I_h[\overline{U}_{k,h} \wedge \Psi])
\]

\[
+ (\partial_t U_{k,h}, I_h[\overline{U}_{k,h} \wedge \Psi] - \overline{U}_{k,h} \wedge \Psi) + (\partial_t U_{k,h}, [\overline{U}_{k,h} - u] \wedge \Psi) + (\partial_t U_{k,h} - u, \wedge \Psi).
\]

The properties of \((\cdot, \cdot)_h, W^{1,2}(\Omega)\)-stability of \(I_h\), and \(\|\overline{U}_{k,h}\|_{L^\infty} \leq 1\) yield

\[
|\partial_t U_{k,h}, I_h[\overline{U}_{k,h} \wedge \Psi])_h - (\partial_t U_{k,h}, I_h[\overline{U}_{k,h} \wedge \Psi])| \leq Ch\|\partial_t U_{k,h}\| \|\nabla I_h[\overline{U}_{k,h} \wedge \Psi]\| \leq Ch\|\partial_t U_{k,h}\| (\|\nabla \overline{U}_{k,h}\| + 1)\|\Psi\|_{W^{1,\infty}}.
\]

Similarly,

\[
|\partial_t U_{k,h}, I_h[\overline{U}_{k,h} \wedge \Psi] - \overline{U}_{k,h} \wedge \Psi)| \leq Ch\|\partial_t U_{k,h}\| (\|\nabla \overline{U}_{k,h}\| + 1)\|\Psi\|_{W^{1,\infty}}.
\]

Convergence towards zero \((h \to 0)\) of the last two terms in (3.12) follows from \(\overline{U}_{k,h} \to u\) in \(L^2(\Omega_T, \mathbb{R}^m)\), and \(\partial_t U_{k,h} \to \partial_t u\) in \(L^2(\Omega_T, \mathbb{R}^m)\), and (3.1), (3.5). Summing up, we find for \(k \leq \tilde{C}h^2\),

(3.13)

\[
\lim_{k,h \to 0} \int_0^T (\partial_t U_{k,h}, \overline{U}_{k,h} \wedge \Psi)_h dt = \int_0^T (\partial_t u, u \wedge \Psi) dt \quad \forall \Psi \in C^\infty(\overline{\Omega_T}, \mathbb{R}^m).
\]

Next, we wish to verify for the second term in (3.11) that in case \(k \leq \tilde{C}h^2\),

(3.14)

\[
\lim_{k,h \to 0} \int_0^T (\nabla U_{k,h}, \nabla I_h[\overline{U}_{k,h} \wedge \Psi]) dt = \int_0^T (\nabla u, \nabla [u \wedge \Psi]) dt \quad \forall \Psi \in C^\infty(\overline{\Omega_T}, \mathbb{R}^m).
\]
Therefore, on using the identities $(\nabla U_{k,h}^r, \nabla \{U_{k,h}^r \wedge \Psi\}) = (\nabla U_{k,h}^r, U_{k,h}^r \wedge \nabla \Psi)$ and $(\nabla u, \nabla \{u \wedge \Psi\}) = (\nabla u, u \wedge \nabla \Psi)$ almost everywhere,

$$
\int_0^T (\nabla U_{k,h}^r, \nabla I_h[\overline{U}_{k,h}^r \wedge \Psi]) - (\nabla u, \nabla u \wedge \Psi) \, dt = \int_0^T (\nabla U_{k,h}^r, \nabla \{I_h[\overline{U}_{k,h}^r \wedge \Psi] - \overline{U}_{k,h}^r \wedge \Psi\}) \, dt
$$

$$
+ \int_0^T (\nabla U_{k,h}^r, [\overline{U}_{k,h}^r - u] \wedge \nabla \Psi) \, dt + \int_0^T (\nabla [\overline{U}_{k,h}^r - u], u \wedge \nabla \Psi) \, dt =: I + II + III.
$$

We compute $I \leq C h \|\nabla U_{k,h}^r\|_2 \|\nabla U_{k,h}^r\|_2 + 1 \|\Psi\|_{W^{2,\infty}}$, by an interpolation estimate, using $\partial^2 U_{k,h}^r|_K = 0$ for all $K \in T_h$. For the terms $II$ resp. $III$, we use $\overline{U}_{k,h}^r \to u$ in $L^2(\Omega, \mathbb{R}^m)$, and $\nabla U_{k,h}^r \to \nabla u$ in $L^2(\Omega, \mathbb{R}^m)$, respectively to conclude that $II, III \to 0$, for $k \leq Ch^2$, and $(k, h) \to 0$. Therefore, the limit $u : \Omega_T \to \mathbb{R}^m$ satisfies (3.2).

\[ \square \]

4. Wave map to the sphere

We recall the notion of weak solutions to (1.5)–(1.7). Below, let $E(u, w) := \frac{1}{2} (\|u\|^2 + \|\nabla w\|^2)$.

**Definition 4.1.** Given $T > 0$ and $(u_0, v_0) \in W^{1,2}(\Omega, \mathbb{R}^{m-1}) \times L^2(\Omega, \mathbb{R}^m)$ with $(u_0, v_0) = 0 \ a.e. \ in \ \Omega$, we call $u : \Omega_T \to \mathbb{R}^m$ a weak solution of (1.5)–(1.7) if (i) $D u \in L^2(\Omega_T, \mathbb{R}^m)$, (ii) $|u| = 1$ almost everywhere in $\Omega_T$,

$$
(iii) \quad - \int_0^T (u_t \wedge u, \Phi_t) \, dt + \int_0^T (\nabla u \wedge u, \nabla \Phi) \, dt = (v_0 \wedge u_0, \Phi(0, \cdot))
$$

\quad $\forall \Phi \in C_0^\infty([0, T); W^{1,2}(\Omega_T, \mathbb{R}^m))$,

$$
(iv) \quad E(u(t, \cdot), u(t, \cdot)) \leq E(v_0, u_0) \ \ \forall t \geq 0,
$$

$$
(v) \quad u(t, \cdot) \to u_0 \ in \ W^{1,2}(\Omega; \mathbb{R}^m), \ \ \ u_t(t, \cdot) \to v_0 \ in \ L^2(\Omega, \mathbb{R}^m) \ \ \ (t \to 0).
$$

We numerically approximate weak solutions of (1.5)–(1.7). Next, we give an explicit formula for $\lambda_{n+1}$ in Algorithm B to study well-posedness, which is again obtained by choosing $\Phi = U^{n+1/2}(z) \varphi_z$.

**Algorithm B.** Given $U^n, U^{n-1} \in V_h$, find $(U^{n+1}, \lambda^{n+1}) \in V_h \times V_h$, such that for all $\Phi \in V_h$ and all $z \in N_h$, there holds

$$
(d_{h}^2 U^{n+1}, \Phi)_h + (\nabla U^{n+1/2}, \nabla \Phi) = \left(\lambda^{n+1} U^{n+1/2}, \Phi\right)_h,
$$

$$
\lambda^{n+1}(z) = \begin{cases} 0 & \text{for } U^{n+1/2}(z) = 0, \\ -\frac{1}{2} \|d_t U^n(z) \|^2 + (d_t U^n(z), d_t U^{n+1}(z)) + (\nabla U^{n+1/2}(z), U^{n+1/2}(z) \nabla \varphi_z) \| \varphi_z \|^2 & \text{else} 
\end{cases}
$$

We set $U^1 = (1 - \mu) U^0 + k \mathbf{V}^0$ with the given initial velocity $\mathbf{V}^0$ and $\mu(z) = 1 - (1 - k^2 \|\mathbf{V}^0(z)\|^2)^{1/2}$ for $z \in N_h$. Let $\mathbf{V}^n := d_t U^n$ for $n \geq 1$. Below, the discrete energy is denoted as

$$
E_h(\mathbf{V}^n, W^n) = \frac{1}{2} (\|W^n\|^2 + \|\nabla W^n\|^2).
$$

In the following, restricted choices $k = O(h^\min(d/2, 3))$, and quasiuniform meshes $T_h$ are sufficient to verify solvability of Algorithm B. The proof uses a regularization in a first step to apply Brouwer’s theorem; then, solutions are shown to satisfy discrete versions of the sphere constraint and the energy law in the case of a mesh constraint, and converge to weak solutions of (1.5)–(1.7).

**Lemma 4.1.** Let $T_h$ be a quasiuniform triangulation of $\Omega \subset \mathbb{R}^d$, and $(U_0, V_0) \in V_h \times V_h$ with $|U_0(z)| = 1$ and $(U_0(z), V_0(z)) = 0$ for all $z \in N_h$. For $n \geq 1$, for sufficiently small
\[ \tilde{C} = \tilde{C}(\Omega, \mathcal{T}_h) > 0 \] independent of \( k, h > 0 \) such that \( k \leq \tilde{C} h^\min\{d/2,1\} \), there exists \( U^{n+1} \in V_h \), which satisfies Algorithm \( B \), has \( \|U^{n+1}(z)\| = 1 \) for all \( z \in \mathcal{N}_h \), and

\[ E_h(V^{N+1}, U^{N+1}) + \frac{k^2}{2} \sum_{n=0}^{N} \|d_t V^{n+1}\|_h^2 = E_h(V^0, U^0) \quad (N \geq 0). \]

A verification of this lemma follows the steps of the proof of Lemma 3.1 in the present case.

**Proof.** The discrete energy law (4.1) follows from the first equation in Algorithm \( B \), on choosing \( \Phi = d_t U^{n+1} \).

Step 1. Fix \( n \geq 0 \). For every \( \varepsilon > 0 \), and all \( \Phi \in V_h \), define the continuous function \( F_\varepsilon : V_h \to V_h \), where

\[ (F_\varepsilon(W), \Phi) := \frac{2}{k^2} (W + U^{n-1/2} - 2U^n, \Phi)_h + (\nabla W, \nabla \Phi) - \sum_{z \in \mathcal{N}_h} \left[ I^\varepsilon_z(W; \Phi) + II^\varepsilon_z(W; \Phi) \right], \]

for

\[ I^\varepsilon_z(W; \Phi) := \left( -\frac{1}{2} \left( |d_t U^n(z)|^2 + \frac{2}{k} \langle d_t U^n(z), W(z) - U^n(z) \rangle \right) \right)_{\tilde{\varphi}_z W, \Phi}, \]

\[ II^\varepsilon_z(W; \Phi) := \left( \frac{\langle \nabla W, W(z) \otimes \tilde{\varphi}_z \rangle}{\beta_z \max \{ |W|^2, \varepsilon \}} \right)_{\tilde{\varphi}_z W, \Phi}. \]

We compute

\[
\sum_{z \in \mathcal{N}_h} I^\varepsilon_z(W; W(z)_{\tilde{\varphi}_z}) \leq \frac{|W(z)|^2}{\max \{ |W(z)|^2, \varepsilon \}} \left[ C d_t U^n \|W^n\|_h^2 + \frac{1}{4k^2} \|W - U^n\|_h^2 \right] \\
\leq C d_t U^n \|W^n\|_h^2 + \frac{1}{4k^2} \|W - U^n\|_h^2,
\]

and

\[ II^\varepsilon_z(W; W(z)_{\tilde{\varphi}_z}) = \frac{|W(z)|^2}{\max \{ |W(z)|^2, \varepsilon \}} (\nabla W, W(z) \otimes \tilde{\varphi}_z) \\
\leq \left( \|\nabla W\|, |W(z)|_{\tilde{\varphi}_z} \right) \|\nabla W\|_{\sup \{\tilde{\varphi}_z\}} \\
\leq C h^{-1} \|\nabla W\|_{\sup \{\tilde{\varphi}_z\}}. \]

For all \( W = \Phi \) such that \( \|W\|_h \geq G \{ |U^{n-i}|_{W^{1,2}} \}_{i=0,1}, |d_t U^n|_h \} > 0 \) sufficiently large, we then find for sufficiently small, positive \( \tilde{C} \equiv \tilde{C}(\Omega) \), and values \( k \leq \tilde{C} h \), using Young’s inequality, and the fact that the number of nodes \( y \in \mathcal{N}_h \) such that \( (\nabla \tilde{\varphi}_y, \nabla \tilde{\varphi}_z) \neq 0 \) is bounded independent from \( h > 0 \),

\[
(F_\varepsilon(W), W)_h \geq \frac{2}{k^2} (\|W\|_h^2 - 4|U^{n-1/2}, W|_h - 2(U^n, W)_h) + \|\nabla W\|^2 \\
-C d_t U^{n-1/2} \|W - U^n\|_h^2 - \frac{1}{4k^2} \|W - U^n\|_h^2 - C h^{-1} \|\nabla W\|_{\sup \{\tilde{\varphi}_z\}} \\
\geq \frac{2}{k^2} \|W\|_h \left( 1 - \frac{C k^2}{h^2} \right) \|W\|_h - 4\|U^{n-1/2}\|_h - 4\|U^n\|_h + \|\nabla W\|^2 \geq 0.
\]

and Brouwer’s fixed-point theorem then implies existence of \( U^{n+1} \in V_h \), such that \( F_\varepsilon(U^{n+1/2}) = 0 \).
Step 2. We show that $U^{n+1/2} \in V_h$ solves $F_0(U^{n+1/2}) = 0$. For this purpose, it suffices to show for all $z \in N_h$ (parallelogram identity)

$$2|U^{n+1/2}(z)|^2 = 1 + |U^{n+1}(z)|^2 - \frac{k^2}{2}|d_tU^{n+1}(z)|^2 \geq 1 - \frac{k^2}{2}|d_tU^{n+1}(z)|^2 > 0.$$  

The iterate $U^{n+1} := 2U^{n+1/2} - U^n \in V_h$ satisfies for all $\Phi \in V_h$,

$$\left(d_t^2U^{n+1}, \Phi \right)_h + (\nabla U^{n+1}, \nabla \Phi) = - \sum_{z \in N_h} I_z(U^{n+1/2}; \Phi) + II_z(U^{n+1/2}; \Phi).$$

On putting $\Phi = d_tU^{n+1}$, and using $|U^{n+1}(z)|^2 = |U^n(z)|^2$, for all $z \in N_h$ yields

$$\frac{1}{2}d_t^2 \left[|d_tU^{n+1}|_{h}^2 + ||\nabla U^{n+1,2}||^2 + \frac{k^2}{2}d_t^2U^{n+1,2}_{h} \right] = 0.$$  

By inverse estimate, for values $k \leq \tilde{C}h$,

$$\frac{k^2}{2}||d_tU^{n+1}||_{L^\infty}^2 \leq Ck^2h^{-d}d_t^2U^{n+1,2}_{h} \leq Ck^2h^{-d} \left[||d_tU^n||_{h}^2 + ||\nabla U^n||_{L^\infty}^2 \right].$$

Hence, assertion (4.3) is valid for values $k \leq \tilde{C}h^{d/2}$, thanks to (4.1).

Similarly, we may derive $k \leq \tilde{C}h^2$ as another sufficient bound to verify (4.3); on setting $\Phi = d_tU^{n+1}(z)\varphi_z$ for $z \in N_h$ in (4.4), using $|U^{n+1}(z)|^2 = |U^n(z)|^2$, and inverse estimates, we obtain

$$\beta_z^2 \left[d_t^2U^{n+1}(z)_{h}^2 + k^2 d_t^2U^{n+1}(z)_{h}^2 \right] \leq \left|(\nabla U^{n+1}, z)_{h}^2 + d_tU^{n+1}(z)\nabla \varphi_z \right| \leq d_tU^{n+1}(z)2C^{-2} ||U^{n+1/2}||_{L^\infty}^2 \beta_z.$$  

By binomial formula, $d_t[|\varphi^n|^2] = \left(|\varphi^n| + |\varphi^{n-1}|\right)d_t\varphi^n$ for $n \geq 1$, and a given sequence $\{\varphi^n\}_{n \geq 0}$, and we then conclude

$$d_tU^{n+1}(z)_{h} \leq \tilde{C}h^{-2} \forall z \in N_h.$$  

Then, given $T > 0$, by discrete Gronwall’s lemma there exists $\tilde{C} \equiv \tilde{C}T, \tilde{C} > 0$, such that for $k \leq \tilde{C}h^2$ there holds $k|d_tU^{n+1}(z)| \leq 1$.

Step 3. The last step deletes the first possibility in (4.1), provided $k \leq \tilde{C}h^{\min\{d/2, 1\}}$. In order to compute $\lambda^{n+1}(z)$, for every $z \in N_h$, we put $\Phi = U^{n+1/2}(z)\varphi_z$. For the leading term, we find

$$\left<d_t^2U^{n+1}(z), U^{n+1/2}(z)\right> = -\frac{1}{2}\left[|d_tU^n(z)|_{h}^2 + d_tU^n(z), d_tU^{n+1}(z)\right],$$

thanks to $d_t|U^{n+1}(z)|_{h}^2 = 0$ for all $z \in N_h$. \[\square\]

Convergence behavior of iterates $\{U^n\} \subset V_h$ of Algorithm (B) towards weak solutions of (1.5)–(1.7) for $(k, h) \rightarrow 0$ is verified below. In the sequel, given $\{\Phi^n\} \subset V_h$, we define $\Phi_{k, h} : \Omega_T \rightarrow \mathbb{R}^m$, where for all $(t, x) \in [t_n, t_{n+1}) \times \Omega$,

$$\Phi_{k, h}(t, x) := \frac{t-t_n}{k}\Phi^{n+1}(x) + \frac{t_{n+1}-t}{k}\Phi^n(x),$$

$$\Phi^+(t, x) := \Phi^{n+1}(x), \quad \Phi^-(t, x) := \Phi^{n+1/2}(x).$$

Subsequently, we drop sub-indices $k, h$ and use $(U^+, \bar{U}, \mathcal{U})$ resp. $(\lambda^+, \lambda)$, and $(V^+, V)$ to stand for $(U^+_{k, h}, \bar{U}_{k, h}, \mathcal{U}_{k, h})$, resp. $(\lambda^+_{k, h}, \lambda_{k, h})$, and $(V^+_{k, h}, V_{k, h})$. For $\Phi \in C_0^\infty([0, T] ; V_h)$, on putting $V^{n+1} = d_tU^{n+1}$, we may rewrite the first equation of Algorithm B as follows,

$$\int_0^T \left[-(V_t, \Phi) + (\nabla U, \nabla \Phi) - (\lambda^+ U, \Phi) \right] dt = 0.$$  

We first derive the following reformulation of Algorithm B.\[10\]
Lemma 4.2. Suppose that the assumptions of Lemma 4.1 are valid. There holds for all \( \Psi \in C^\infty_0([0,T);C^\infty(\Omega;\mathbb{R}^m)) \),

\[
\left| \int_0^T \left[ -\left( U_t, [\bar{U} \wedge \Psi]_t \right)_h + \left( \nabla \bar{U}, \nabla [\bar{U} \wedge \Psi] \right)_h \right] \ dt - \left( \bar{V}^0, \bar{U}(0, \cdot) \wedge \Psi(0, \cdot) \right)_h \right| 
\]

(4.7)

\[ \leq \left| \int_0^T \left( V^+ - V, [\bar{U} \wedge \Psi]_t \right)_h \ dt \right| + Ck^{1/2}E_h(\bar{V}^0, \bar{V}^0) \| \Psi \|_{L^\infty(\Omega_T)}, \]

where \( \bar{U}(0, \cdot) = \frac{1}{2} \bar{V}^0 + \bar{U}^0 \).

Proof. Let \( \Psi \in C^\infty_0([0,T);C^\infty(\Omega;\mathbb{R}^m)) \), and take \( \Phi = I_h[\bar{U} \wedge \Psi] \). We use the following identity in \( \Omega \),

\[
\bar{U}(t, \cdot) = U(t, \cdot) + \left[ \frac{1}{2}(t_{n+1} + t_n) - t \right] V^+(t, \cdot) \quad \forall t \in [t_n, t_{n+1})
\]

(4.8)

to conclude \( (V_t, [\bar{U} - U] \wedge \Psi)_h \leq \frac{1}{2} \| V_t \|_h \| V^+ \|_h \| \Psi \|_{L^\infty} \), and obtain the following bound by (4.1), and Young’s inequality after integration in time,

\[
\int_0^T (V_t, [\bar{U} - U] \wedge \Psi)_h \ dt \leq Ck^{1/2} \left( k \int_0^T \| V_t \|_h^2 \ dt \right)^{1/2} \| \Psi \|_{L^\infty(\Omega_T)} \leq C \sqrt{k} E_h(\bar{V}^0, \bar{V}^0) \| \Psi \|_{L^\infty(\Omega_T)}. 
\]

For the remaining term, we use integration by parts, and \( V^+(t, \cdot) = U_t(t, \cdot) \) in \( \Omega \), for all \( t \in [t_n, t_{n+1}) \),

\[
\int_0^T -(V_t, [\bar{U} \wedge \Psi]_t)_h \ dt = \int_0^T \left( -[V - V^+] - U_t, [\bar{U} \wedge \Psi]_t \right)_h \ dt.
\]

Putting things together, (4.6) then implies the assertion of the Lemma. \( \Box \)

The first term in (4.7) may be restated as a controllable perturbation of \( - \int_0^T (U_t, [U \wedge \Psi]_t)_h \ dt \): we restate (4.8) as \( \bar{U}(t, \cdot) = U(t, \cdot) + \frac{k}{2}(1 - 2\frac{t - t_n}{k}) V^+(t, \cdot) \), for \( t \in [t_n, t_{n+1}) \), to find

\[
\left| \int_0^T \left( U_t, \langle [U + \frac{k}{2}(1 - 2\frac{t - t_n}{k}) V^+] \wedge \Psi \rangle_t \right)_h \ dt \right| 
\]

(4.9)

\[
\leq \frac{k}{2} \int_0^T \left| \left( U_t, \langle (1 - 2\frac{t - t_n}{k}) V - V^+ \rangle \wedge \Psi \rangle_t \right)_h \right| \ dt 
\]

\[
\leq Ck^{1/2} \left( k \int_0^T \| V_t \|_h^2 \ dt \right)^{1/2} \| \Psi \|_{L^\infty(\Omega_T)} + Ck \| U_t \|_{L^\infty(L^2)} \| V \|_{L^\infty(L^2)} \| \Psi \|_{L^1(L^\infty)} 
\]

\leq Ck^{1/2} \left[ \| \Psi \|_{L^\infty(\Omega_T)} + k^{1/2} \| \Psi \|_{L^1(L^\infty)} \right],
\]

where again we use additional control over \( V_t \) as is given in Lemma 4.1. — Effects like numerical integration, interpolation, and combination of successive iterates in (4.7) are considered next to establish convergence of iterates of Algorithm B to weak solutions of (1.5)–(1.7).

Theorem 4.1. Let the assumptions of Lemma 4.1 be valid, and \( U^0 \rightharpoonup u_0 \in W^{1,2}(\Omega, \mathbb{R}^m) \) resp. \( V^0 \rightharpoondown v_0 \in L^2(\Omega, \mathbb{R}^m) \), for \( h \to 0 \). There exist \( u \in L^\infty(0, T, W^{1,2}(\Omega, \mathbb{R}^m)) \) \( \cap W^{1,\infty}(0, T, L^2(\Omega, \mathbb{R}^m)) \), and a subsequence \( \{ \bar{U}_{k,h} \} \) such that for \( (k, h) \to 0 \)

\[
\bar{U}_{k,h} \rightharpoonup u \quad \text{in} \quad L^\infty(0, T; W^{1,2}(\Omega, \mathbb{R}^m)), \\
(U_{k,h})_t \rightharpoonup u_t \quad \text{in} \quad L^\infty(0, T; L^2(\Omega, \mathbb{R}^m)).
\]

Moreover, \( u : \Omega_T \to \mathbb{R}^m \) is a weak solution of (1.5)–(1.7).

Throughout the proof, we again drop sub-indices.
Proof. Step 1. The bounds of Lemma 4.1 yield the existence of $u \in L^\infty(0, T; W^{1,2}(\Omega, \mathbb{R}^m)) \cap W^{1,\infty}(0, T; L^2(\Omega, \mathbb{R}^m))$, such that for $k \leq \tilde{C}h_{\text{min}}^{d/2,2}$ and $h \to 0$,

$$
\begin{align*}
U, U^+, U^+ & \rightharpoonup u \quad \text{in} \quad L^\infty(0, T; W^{1,2}(\Omega, \mathbb{R}^m)), \\
U, U^+, U & \to u \quad \text{in} \quad L^2(\Omega_T, \mathbb{R}^m), \\
U_t, V, V^+ & \rightharpoonup u \quad \text{in} \quad L^\infty(0, T; L^2(\Omega, \mathbb{R}^m)).
\end{align*}
$$

(4.10)

Since $|U^+| = 1$ for all $z \in \mathcal{N}_h$ and all $t \in [0, T]$, there holds $\mathcal{I}_h[|U^+|^2] = 1$ for all $(t, x) \in \overline{\Omega_T}$, and for all $K \in \mathcal{I}_h$

$$
|||U^+|^2 - 1||_L^2(K) \leq Ch||\nabla U^+||_L^2(K).
$$

Consequently, $|U^+| \to 1$ almost everywhere in $\Omega_T$, and hence $|u| = 1$ almost everywhere.

Step 2. We compute

$$
\left| (U_t, U \wedge \Psi_t)_h - (u_t, u \wedge \Psi_t) \right| \leq \left| (U_t, \mathcal{I}_h(U \wedge \Psi))_h - (U_t, \mathcal{I}_h(U \wedge \Psi_t)) \right| + \left| (\mathcal{I}_h(U \wedge \Psi) - U \wedge \Psi_t) + (u_t - U_t, u \wedge \Psi_t) \right| =: I + \ldots + IV.
$$

We use properties of $(\cdot, \cdot)_h$, $W^{1,2}(\Omega)$-stability of $\mathcal{I}_h$, and $||U||_L^\infty \leq 1$ to find

$$
I \leq Ch||U_t|| ||\mathcal{I}_h(U \wedge \Psi)|| \leq Ch||U_t|| (||\nabla U|| + 1)||\Psi_t||_W^{1,\infty}.
$$

The term $II$ can be bounded correspondingly. Convergence towards zero $(h \to 0)$ of the terms $III$ and $IV$ follows from $U \to u$ in $L^2(\Omega_T, \mathbb{R}^m)$, and $U_t \to u_t$ in $L^2(\Omega_T, \mathbb{R}^m)$. Hence, for $k \leq \tilde{C}h_{\text{min}}^{d/2,2}$,

$$
\lim_{k, h \to 0} \int_0^T (U_t, U \wedge \Psi)_h \ dt = \int_0^T (u_t, u \wedge \Psi) \ dt \quad \forall \Psi \in C^0_0((0, T); C^\infty(\Omega, \mathbb{R}^m)).
$$

Next, we verify that the limit for the second term in (4.7) for $k \leq \tilde{C}h_{\text{min}}^{d/2,2}$ is

$$
\lim_{k, h \to 0} \int_0^T (\nabla U, \nabla \mathcal{I}_h(U \wedge \Psi)) \ dt = \int_0^T (\nabla u, \nabla [u \wedge \Psi]) \ dt \quad \forall \Psi \in C^0_0((0, T); C^\infty(\Omega, \mathbb{R}^m)).
$$

For this purpose, since $\langle \nabla U, \nabla [U \wedge \Psi] \rangle = \langle \nabla U, \nabla \Psi \rangle$, and $\langle \nabla U, \nabla [u \wedge \Psi] \rangle = \langle \nabla u, u \wedge \Psi \rangle$

almost everywhere,

$$
(\nabla U, \nabla \mathcal{I}_h(U \wedge \Psi)) - (\nabla u, \nabla [u \wedge \Psi]) = (\nabla U, \nabla [\mathcal{I}_h(U \wedge \Psi) - U \wedge \Psi]) + (\nabla U, [U - u] \wedge \Psi) + (\nabla U - u) \wedge \Psi =: I + II + III.
$$

We compute $I \leq Ch||\nabla U||(||\nabla U|| + 1)||\Psi||_W^{1,\infty}$, by an interpolation estimate, using $D^2\mathcal{I}_h = 0$ for all $K \in \mathcal{I}_h$. For the terms $II$ resp. $III$, we use $U \to u$ in $L^2(\Omega_T, \mathbb{R}^m)$, and $\nabla U \to \nabla u$ in $L^2(\Omega_T, \mathbb{R}^{md})$, respectively to conclude that $\int_0^T II \ dt, \int_0^T III \ dt \to 0$, for $k \leq \tilde{C}h_{\text{min}}^{d/2,2}$, and $h \to 0$. Therefore, assertion (4.13) is valid, and hence the limit $u : \Omega_T \to \mathbb{R}^m$ satisfies (4.1).

Convergence $(V^0, \mathcal{I}_h(0 \cdot \wedge \Psi(0 \cdot )))_h \to (v_0, u_0 \wedge \Psi(0 \cdot ))$, for $k \leq \tilde{C}h_{\text{min}}^{d/2,2}$, and $h \to 0$ follows from properties of $(\cdot, \cdot)_h$, and $V^0 \to v_0$ in $L^2(\Omega, \mathbb{R}^m)$, resp. $U^0 \to u_0$ in $W^{1,2}(\Omega, \mathbb{R}^m)$. Finally, since $|U| \leq 1$, we conclude similar to (4.9)

$$
\int_0^T (V^+ - V, [U \wedge \Psi]_h) \ dt \leq Ck^{1/2} \left( \int_0^T ||V_t||^2 \ dt \right)^{1/2} \left( \int_0^T ||U_t||^2 \ dt \right)^{1/2} (1 + ||\Psi||_W^{1,\infty}(\Omega_T)),
$$

for the last term in (4.7). Therefore, $u : \Omega_T \to \mathbb{R}^m$ satisfies assertion (iii) of Definition 4.1.

Step 3. We verify assertion (iv) of Definition 4.1. $u_0 = \lim_{h \to 0} \lim_{k, h \to 0} U(t \cdot , \cdot)$ in $L^2(\Omega, \mathbb{R}^m)$ follows from (4.10). It remains to show $U(t \cdot , \cdot) \to v_0$ in $L^2(\Omega, \mathbb{R}^m)$ as $t \to 0$. Therefore, multiply
\[ u \wedge u = 0 \] with \( \Psi \in C_\infty^\infty([0, T); C_0^\infty(\Omega, \mathbb{R}^m)) \), integrate by parts on \( \Omega_T \), and subtract the resulting equation from (4.7). We find for the limit \( k, h \to 0 \),

\[ (u(0, \cdot) - v_0, u_0 \wedge \Psi) = 0 \quad \forall \Psi \in C_0^\infty([0, T); C_0^\infty(\Omega, \mathbb{R}^m)) .\]

On noting \( \langle v_0(x), u_0(x) \rangle = \langle u(0, x), u_0(x) \rangle = 0 \) for almost every \( x \in \Omega \), it follows from the vector identity \( v = (u, v)u - u \wedge (u \wedge v) \) — with \( v = u(0, \cdot) - v_0 \) and \( u = u_0 \) — that \( u(t, \cdot) \to v_0 \) in \( L^2(\Omega, \mathbb{R}^m) \) as \( t \to 0 \).

We also need to show \( u(t, \cdot) \to v_0 \) in \( L^2(\Omega, \mathbb{R}^m) \) as \( t \to 0 \). By weak lower semicontinuity of \( L^2 \)-norm and Fatou’s lemma

\[ \|Du(t, \cdot)\|_{L^2} \leq \liminf_{k, h \to 0} \|DU(t, \cdot)\|_{L^2} \quad t \geq 0. \]

Hence, for all \( t \geq 0 \), because of properties of \( (\cdot, \cdot)_h \), and assumptions on initial data,

\[ E(u(t, \cdot), u(t, \cdot)) \leq \liminf_{k, h \to 0} E(U(t, \cdot), U(t, \cdot)) = \liminf_{k, h \to 0} E_h(U(t, \cdot), U(t, \cdot)) \leq E(v_0, u_0). \]

Therefore,

\[ \limsup_{t \to 0} \|u(t, \cdot)\|_{L^2} \leq \|v_0\|_{L^2}, \quad \limsup_{t \to 0} \|\nabla u(t, \cdot)\|_{L^2} \leq \|\nabla u_0\|_{L^2}, \]

and the weak convergence \( u(t, \cdot) \to v_0 \) in \( L^2(\Omega, \mathbb{R}^m) \) and \( \nabla u(t, \cdot) \to \nabla u_0 \) in \( L^2(\Omega, \mathbb{R}^{md}) \) implies strong convergence \( \nabla u(t, \cdot) \to \nabla v_0 \) in \( L^2(\Omega, \mathbb{R}^{md}) \) as \( t \to 0 \). Consequently, \( u : \Omega_T \to \mathbb{R}^m \) attains prescribed initial data continuously in \( W^{1, 2}(\Omega, \mathbb{R}^m) \times L^2(\Omega, \mathbb{R}^m) \).

Since all requirements of Definition 4.1 are verified, hence, the map \( u : \Omega_T \to \mathbb{R}^m \) is a weak solution to (1.5)–(1.7). The proof is complete. \( \square \)

**Remark 4.1.** A symmetric variant of Algorithm B is: For \( n = 1, 2, \ldots, \) find \( (U^{n+1}, \lambda^n) \in V_h \times V_h \), such that for all \( \Phi \in V_h \), and all \( z \in N_h \) there holds

\[ \left( \frac{d^2}{dt^2} U^{n+1}, \Phi \right)_h + \left( \frac{1}{2} \nabla \left[ U^{n+1} + U^{n-1} \right], \nabla \Phi \right)_h = \left( \frac{\lambda^n}{2} \left[ U^{n+1} + U^{n-1} \right], \Phi \right)_h, \]

\[ \lambda^n(z) = \begin{cases} 0 & \text{for } [U^{n+1} + U^{n-1}](z) = 0, \\ \frac{-\langle d_z U^n(z), d_z U^{n+1}(z) \rangle}{\|d_z U^{n+1} + U^{n-1}\|^2} + \frac{1}{\|d_z U^{n+1} + U^{n-1}\|^2} \langle \nabla U^{n+1} + U^{n-1}, \nabla \Phi \rangle & \text{else}. \end{cases} \]

This choice of \( \lambda^n \) again ensures that \( |U^{n+1}(z)| = 1 \) for all \( z \in N_h \). The discrete energy is denoted as \( \tilde{E}_h(V^n, \{U^{n-j}\}_{j=0}^1) = \frac{1}{2} \left[ \|V^n\|_h^2 + \frac{1}{2} (\|\nabla V^n\|^2 + \|\nabla U^{n-1}\|^2) \right] \), for \( V^n := d_t U^n \). Again, existence of solutions \( U^{n+1} \in V_h \) in the case \( k \leq \tilde{C} h^{\min(d/2, 2)} \) can be shown, and

\[ \tilde{E}_h(V^{N+1}, \{U^{N+1-j}\}_{j=0}^1) = \frac{1}{2} \left[ \|V^0\|_h^2 + \frac{1}{2} (\|\nabla U^0\|^2 + \|\nabla U^0\|^2) \right] \quad (N \geq 0). \]

However, convergence for \( (k, h) \to 0 \) is not clear because of the absence of the second term on the left-hand side of (4.1), which gives enough control over temporal variations of \( \{d_t U^n\} \) to pass to the limit \( (k, h) \to 0 \) in every term in (4.1).

5. Computational Studies

In this section, we report on practical performance of Algorithms A and B. The nonlinear systems of equations in each time step were approximately solved using fixed-point iterations (which utilize the old \( \lambda^{n+1, \ell} \) defined through the actual iterate \( U^{n+1, \ell} \) to determine the update \( U^{n+1, \ell+1} \)). Both algorithms were implemented in MATLAB with a direct solution of linear systems of equations.
The initial data that we employ for both, the harmonic map heat flow as well as the wave map evolution, in the following two subsections are defined in the following example.

**Example 5.1.** Given \( w > 0 \), let \( \Omega := (0,2+w) \times (0,1) \). With \( r_j \equiv r_j(x) := |x - p_j| \) and 
\[
a_j = a_j(x) := (1 - 2 r_j(x))^4 \quad \text{for} \quad x \in \Omega, \ j = 1, 2, \ \text{and} \ p_1 := (1/2,1/2) \ \text{and} \ p_2 := (3/2,1/2),
\]
we define for \( x = (x_1, x_2) \in \Omega \)
\[
\begin{align*}
\mathbf{u}_0(x) := & \begin{cases} 
(0,0,-1), & x_1 \in (0,1) \ \text{and} \ r_1 \geq 1/2, \\
\frac{(2(x_1-1/2)a_1,2(x_2-1/2)a_2,a_1^2-r_1^2)}{a_1^2+r_1^2}, & x_1 \in (0,1) \ \text{and} \ r_1 \leq 1/2, \\
(0,\sin((x_1-1)\pi/w),\cos((x_1-1)\pi/w)), & x_1 \in (1,1+w) \\
(0,0,1), & x_1 \in (1+w,2+w) \ \text{and} \ r_2 \geq 1/2, \\
\frac{(2(x_1-1/2)a_2,2(x_2-1/2)a_2,a_2^2-r_2^2)}{a_2^2+r_2^2}, & x_1 \in (1+w,2+w) \ \text{and} \ r_2 \leq 1/2.
\end{cases}
\end{align*}
\]

A projection of the nodal interpolant of the vector field \( \mathbf{u}_0 \) onto the \( xy \)-plane is shown in the top plot of Figure 5. For the simulation of the wave flow we also define the initial velocity \( \mathbf{v}_0 := 0 \). All employed triangulations were obtained from uniform refinements of the triangulation \( T_0 \) of \( \Omega \) which consists of \( 6 \) triangles which are all halved squares if \( w = 1 \). The discrete initial data is obtained by nodal interpolation of \( \mathbf{u}_0 \). Unless otherwise stated, we set \( w = 1 \).

### 5.1. Experimental results for the wave map problem

We run Algorithm B for Example 5.1 with the triangulation \( T_3 \) obtained from three uniform (“red”) refinements of \( T_0 \) and with \( k = h/8 \), where \( h = 2^{-3} \). We stopped the time stepping at \( t = 1/4 \), i.e., after 32 time steps, and replaced \( \mathbf{V}(t,\cdot) \) by \( -\mathbf{V}(t,\cdot) \) at \( t = 1/4 \) to reverse the evolution and run another 32 time steps. The numerical results for \( t = 1/4 \) and the almost recovered initial data are shown in the second and third (from top) plot of Figure 5. Owing to an instability related to occurrence of large (maximal) gradients which motivates finite-time blow-up, we can not (approximately) recover the initial data when we reverse the evolution at \( t = 1/2 \), which is beyond the instability; cf. the fourth and fifth plot in Figure 5. This behavior does not improve when we significantly decrease the stopping criterion for the fixed point iteration, i.e., when we solve the nonlinear systems of equations almost exactly.

In order to compare the performance of Algorithm B to the projection strategy proposed in [6] we display in Figure 1 the total energy of the approximations obtained with the two schemes on uniform triangulations with mesh-size \( h = 2^{-3}, 2^{-4} \), and for time-step sizes \( k = h, h/10 \). We observe that the total energy is for all pairs of discretization parameters decreasing for the numerical approximation obtained with Algorithm B. This is not the case for the approximations computed with the explicit projection scheme of [6]; in fact, the energy rapidly increases for \( k = h \) which indicates strong numerical instabilities. Nevertheless, for \( k = h/10 \) all results are qualitatively comparable. The total energy, the kinetic energy \( E_h^\text{kin}(\mathbf{V}(t,\cdot)) := \frac{1}{2} ||\mathbf{V}(t,\cdot)||^2_h \) and the \( W^{1,\infty}(\Omega) \)-semi-norm as functions of time \( t \in (0,1/2) \) for the two different schemes on a triangulation with \( h = 2^{-5} \) and \( k = h/10 \) are displayed in Figure 2. We observe that large gradients occur and that energy is lost when a large change of the \( W^{1,\infty}(\Omega) \)-norms takes place.

The experimental results are slightly different when the symmetric but theoretically unjustified scheme of Remark 4.1 is used to compute numerical approximations. As opposed to Algorithm B and the projection scheme of [6], the evolution can always be reversed. The reported irreversibility in Example 5.1 which is related to a numerical instability when the vectors at \( (1/2,1/2) \) or \( (3/2,1/2) \) changes its direction within a small time interval is different here and the vectors remain fixed when the symmetric scheme is used. Also, there is no loss of (the modified) energy as can be seen in Figure 3. Nevertheless, we emphasize that the symmetric scheme is not known to converge to a weak solution.
Figure 1. Total energy for numerical approximations obtained with Algorithm B and with the projection scheme of [6] for various discretization parameters in the wave map problem defined with initial data from Example 5.1.

Figure 2. Total energy, kinetic energy, and $W^{1,\infty}(\Omega)$-semi-norm for numerical approximations obtained with Algorithm B and with the projection scheme of [6] for fixed discretization parameters in the wave map problem defined with initial data from Example 5.1.
Figure 3. Total energy, kinetic energy, and $W^{1,\infty}(\Omega)$-semi-norm for numerical approximations obtained with the symmetric scheme from Remark 4.1 for fixed discretization parameters in the wave map problem defined with initial data from Example 5.1.

Figure 4. Energy and $W^{1,\infty}$ semi-norm for numerical approximations of the harmonic map heat flow problem obtained with Algorithm A for various discretizations parameters and with initial data defined in Example 5.1.
Figure 5. Numerical solutions obtained with Algorithm B in Example 5.1. Initial data (top plot), numerical approximations at $t = 1/4$ and $t = 1/2$ (second and fourth plot from top), and approximations at $t = 0$ when the evolution is reversed at $t = 1/4$ and $t = 1/2$ (third and fifth plot). All vectors are scaled by the factor $1/8$ for graphical purposes.
5.2. Experimental results for the heat flow problem. Our numerical experiments for the harmonic map heat flow problem based on Algorithm A do not show significant advantages of the proposed scheme over the algorithms developed in [5, 3]. The reason for this is that the fixed point iteration requires in all of our numerical studies that $k \leq h^2/5$, and therefore does not improve existing results. However, for this choice of the time-step size we obtain reasonable results for the evolution defined by the initial data specified in Example 5.1. Figure 6 displays snapshots of the numerical solution for $t = 0, 0.01875, 0.0375, 0.05625, 0.075$. Large (maximal) gradients occur for $t \approx 0.05$ and afterwards the solution appears to be smooth and converges to a steady (uniformly constant) state. We remark that the numerical results do not change qualitatively when we employ other values for the parameter $w$. Rapid decay of the energy accompanied by occurrence of large gradients on each mesh when $k \leq h^2/5$ are the main conclusions of the practical experience with Algorithm A.

5.3. Effect of different winding numbers. As is detailed in [12], weak solutions of the Dirichlet problem for the harmonic map heat flow for $\ell$-equivariant maps, with $\ell = 2$, do not blow up. This is in contrast to the wave-map flow, where finite-time blow-up behavior is still expected; cf. [16, Remark 1.6]. The following example reports on corresponding numerical studies in an equivariant setting but restricted to a square centered around the origin. The initial data that we use are defined as follows.

Example 5.2. Set $\Omega := (-2, 2)^2$ and for $\ell = 1$ or $\ell = 2$ define

$$ u_0(r, \theta) := \begin{pmatrix} \sin \chi(r, \ell \theta) \sin \ell \theta \\ \sin \chi(r, \ell \theta) \cos \ell \theta \\ \cos \chi(r, \ell \theta) \end{pmatrix}, \quad v_0(r, \theta) \equiv 0, $$

where $(r, \theta)$ denotes polar coordinates in $\mathbb{R}^2$ and $\chi(r, \ell \theta) := (r^3/4) \exp(-(4(r-2)/10)^4)$.

We ran Algorithm B in Example 5.2 on uniform triangulations of $\Omega$ with $h = 4 \cdot 2^{-5}$ and $h = 4 \cdot 2^{-6}$ and time-step size defined through $k = h/5$. Figure 7 displays the total energies and $W^{1, \infty}$ seminorm as functions of $t \in [0, 4]$. We observe that large gradients occur for $\ell = 1$ while they do not occur for $\ell = 2$.
